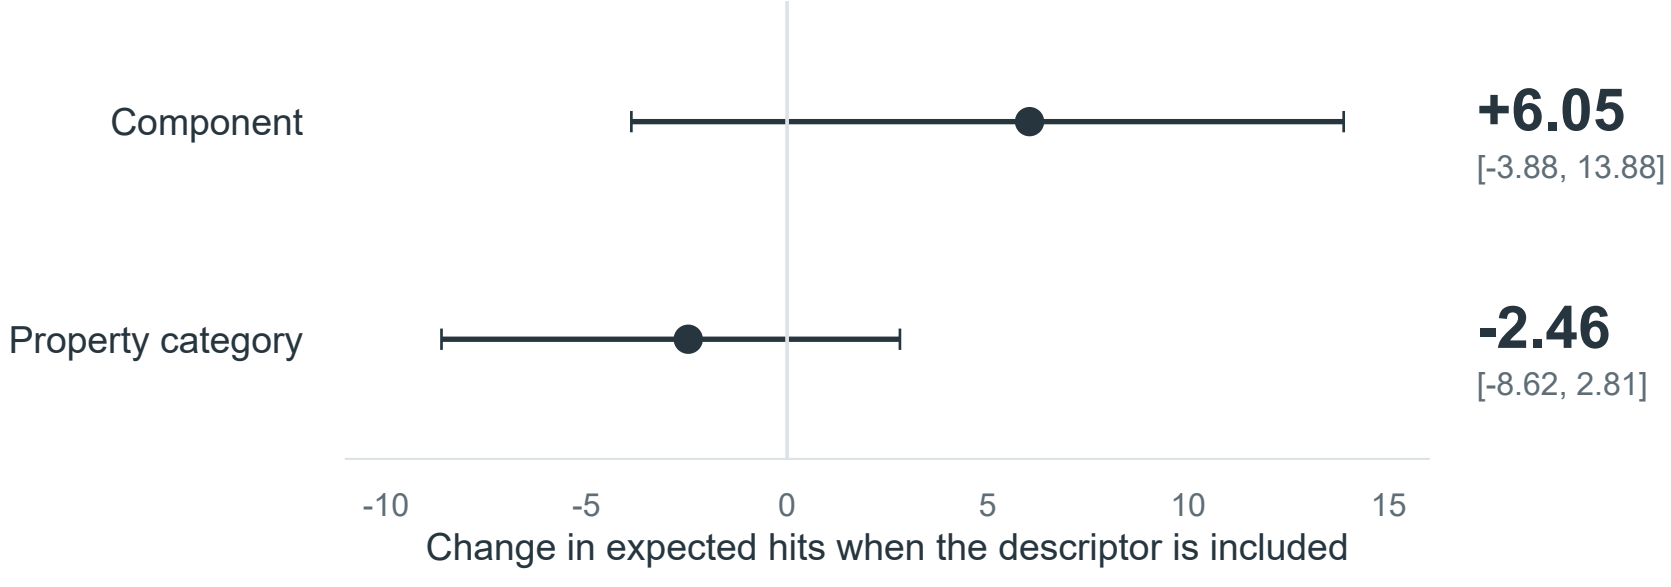
Scene interpretation and model contribution are assessed separately

Four later periods, 152 review slots. Drop one descriptor, refit the model, and compare with the full model.

Expected hits: 54.25 with all descriptors; 48.20 without component; 56.71 without property category.



Lines show paired 95% operator-bootstrap intervals. The full model uses component, material, property category and class location. Differences assess incremental information at a fixed review budget; both intervals include positive and negative changes.
